New Tasks - Organize and execute a series of tasks. Now your Mac can help you stay organized and productive! TypeScript is a language used for development of the browser-based applications. It is an extension of JavaScript, but in the last years it has become one of the most popular languages among other Javascript-based scripts. One of the major benefits of the TypeScript is that it has become the transition language for the developers who

have already worked with Javascript or any other compiled programming language. If you want to start your career with the TypeScript, you should be familiar with some basic concepts. If you are a beginner, you will find here some key TypeScript topics that will help you to understand the basic concepts and start your journey with this advanced programming language. What is TypeScript? The TypeScript is a compiled, statically typed, and type-safe programming language, for which the syntax is very similar to JavaScript. It also has a new module syntax that makes it easier to create large applications. In addition, it uses classes for OOP, which creates even better organized and structured projects. Below, you will find the detailed description of the most important TypeScript features. TypeScript Basic Concepts Typing As the TypeScript is the compiled programming language, you must define the types of the objects or variables at the very first stage. The TypeScript has the same data typing as the JavaScript, so you can make assumptions about the types of the objects,

variables, parameters, and their attributes. One of the benefits of the TypeScript is that you can use it without the strict data typing; in this case, it is possible to use only a string variable. Basically, the TypeScript has two types of typing – strong typing and weak typing. If the data is typed strongly, only the known values are allowed, so you can have a property with only type string. Functions In the TypeScript, all variables and objects have their own types. If you write a variable without declaring its type, TypeScript has the same data typing as the JavaScript, in which the object is not typed by itself, but the properties of this object are. So, when you are working with the TypeScript, it is crucial to declare the type of the variables, parameters, and objects. It is possible to use some more advanced techniques to define the types of the variables and objects, for example, the union, interface, generic, conditional, and ref types. Code Sculpture The TypeScript allows you to declare the modules and classes. The TypeScript is the compiled programming language, so the modules and classes must be

defined in the code. All classes are singletons and only one instance of the class will be available in the entire program. Typing is very important in the TypeScript, but even if it is strongly typed, it has some benefits, for example, it does not
